Introduction

- Theoretical efforts to understanding of GANs focus on statistics or optimization.
- Statistics:
  - In the GAN paper, Goodfellow et al. (2014) linked the min-max formulation and the JS divergence.
  - WGAN (Arjovsky et al., 2017) proposed a loss function based on the Wasserstein distance.
  - Wasserstein distance and JS distance are not generalizable but real metric used in practice is generalizable (Arora et al., 2017).
- Optimization:
  - Cyclic behavior, non-convergence, for min-max optimization: cycle around a stable point to slowly converge or diverge.
  - Sub-optimal local minima issues for GANs: current works only perform local analysis or global analysis with simple setting.
- Therefore, main goal of the paper is to perform global analysis on GANs for general data distribution.
Introduction

* This table does NOT show a complete list of works. The goal is to list various types of works. Only one or two works are listed as examples of that class.
Relativistic GANs

- Discriminator should utilize both real and fake data to measure the reality of samples, therefore, the measurement of absolute reality is substituted with relative reality.
- Having the priori knowledge that input samples consist of half real and half fake samples, discriminator estimates real samples with lower score as the fake samples are more realistic than the real samples.
## Relativistic GANs

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Absolute probability (Standard GAN)</th>
<th>Relative probability (Relativistic average Standard GAN)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real image looks real <strong>and</strong> fake images look fake</td>
<td>$C(x_r) = 8$ [ P(x_r \text{ is bread}) = 1 ]</td>
<td>$C(x_f) = -5$ [ P(x_r \text{ is bread}</td>
</tr>
<tr>
<td>Real image looks real <strong>but</strong> fake images look similarly real on average</td>
<td>$C(x_r) = 8$ [ P(x_r \text{ is bread}) = 1 ]</td>
<td>$C(x_f) = 7$ [ P(x_r \text{ is bread}</td>
</tr>
<tr>
<td>Real image looks fake <strong>but</strong> fake images look more fake on average</td>
<td>$C(x_r) = -3$ [ P(x_r \text{ is bread}) = .05 ]</td>
<td>$C(x_f) = -5$ [ P(x_r \text{ is bread}</td>
</tr>
</tbody>
</table>
Relativistic GANs

- The training is problematic by only pushing $D(fake)$ to 1 and ignoring $D(real)$. 
To make discriminator relativistic, we can sample real/fake data pairs \( \hat{x} = (x_r, x_f) \) with \( D(\hat{x}) = \text{sigmoid}(C(x_r) - C(x_f)) \).

The discriminator estimates the probability that the given real data is more realistic than a randomly sampled fake data.
Therefore, we have loss in general form:

\[\begin{align*}
L_{RGAN}^D &= \mathbb{E}_{(x_r, x_f) \sim (P, Q)} \left[ f_1 \left( C(x_r) - C(x_f) \right) \right] \\
&\quad + \mathbb{E}_{(x_r, x_f) \sim (P, Q)} \left[ f_2 \left( C(x_f) - C(x_r) \right) \right] \\
L_{RGAN}^G &= \mathbb{E}_{(x_r, x_f) \sim (P, Q)} \left[ g_1 \left( C(x_r) - C(x_f) \right) \right] \\
&\quad + \mathbb{E}_{(x_r, x_f) \sim (P, Q)} \left[ g_2 \left( C(x_f) - C(x_r) \right) \right]
\end{align*}\]

The point is to use real/fake paired data for training.
Outline

Introduction

Motivation and Method

Results
Intuition

▶ Suppose we have two real samples $x_1, x_2$ and two generated samples $y_1, y_2$ in one dimension, then we can intuitively illustrate the training process of standard GANs as:

▶ Easily lead to mode collapse.
Intuition

- Having the same setting, the training process of relativistic paired GANs is:

- Seem to have no mode collapse.
To further investigate how pairing influence local minima, the paper sets a two-point case:

- Two real samples $x_1, x_2$ and two generated samples $y_1, y_2$.
- Four states $s_0, s_{1a}, s_{1b}, s_2$ represent $|\{x_1, x_2\} \cap \{y_1, y_2\}| = 0$,
  $y_1 = y_2 \in \{x_1, x_2\}$, $|\{x_1, x_2\} \cap \{y_1, y_2\}| = 1$,
  $\{x_1, x_2\} = \{y_1, y_2\}$.

- $s_0$: no overlap
- $s_2$: perfect match
- $s_{1a}$: mode collapse
- $s_{1b}$: mode dropping
Bad Local Minima

\[ \phi_{JS}(Y, X) = \begin{cases} 
- \log 2 \approx -0.6931 & \text{if } s_2, \\
- \log 2/2 \approx -0.3467 & \text{if } s_{1b}, \\
\frac{1}{4}(2 \log 2 - 3 \log 3) \approx -0.4774 & \text{if } s_{1a}, \\
0 & \text{if } s_0 
\end{cases} \]

where \( \phi_{JS} \) is the divergence measurement in JS-GAN.

Sub-optimal local minima at \( s_{1a} \).
Bad Local Minima

\[ \phi_{RS}(Y, X) = \begin{cases} 
- \log 2 \approx -0.6931 & \text{if } s_2, \\
-\frac{1}{2} \log 2 \approx -0.3466 & \text{if } s_{1a}, s_{1b}, \\
0 & \text{if } s_0 
\end{cases} \]
Theorem 1.
Suppose $x_1, x_2, \ldots, x_n \in \mathbb{R}^d$ are distinct. Suppose $h_1, h_2$ satisfy Assumptions 4.1, 4.2 and 4.3. Then for separable-GAN loss $g_{SP}(Y)$ defined in Eq. (5), we have:
(i) The global minimal value is $-\frac{1}{2} \sup_{t \in \mathbb{R}} (h_1(t) + h_2(-t))$, which is achieved iff $\{y_1, \ldots, y_n\} = \{x_1, \ldots, x_n\}$.
(ii) If $y_i \in \{x_1, \ldots, x_n\}, i \in \{1, 2, \ldots, n\}$ and $y_i = y_j$ for some $i \neq j$, then $Y$ is a sub-optimal strict local minimum. Therefore, $g_{SP}(Y)$ has $(n^n - n!)$ sub-optimal strict local minima.

The theorem is saying that (i) For standard GANs, global minimal achieves when two sets of points perfectly match; (ii) Local minima always exists in some scenarios.
Landscape Results in Function Space

Definition (global-min-reachable)
We say a point $w$ is global-min-reachable for a function $F(w)$ if there exists a continuous path from $w$ to one global minimum of $F$ along which the value of $F(w)$ is non-increasing.

Theorem 2.
Suppose $x_1, x_2, \ldots, x_n \in \mathbb{R}^d$ are distinct. Suppose $h$ satisfies Assumptions 4.4 and 4.5. Then for RpGAN loss $g_R$ defined in Eq. (6): (i) The global minimal value is $h(0)$, which is achieved iff \( \{y_1, \ldots, y_n\} = \{x_1, \ldots, x_n\} \). (ii) Any $Y$ is global-min-reachable for the function $g_R(Y)$.

- Theorem 2 means (i) For RpGAN, global minimal achieves when two sets of points perfectly match; (ii) Only global minima.
Different from before, where we optimize over $y_i$ and $f$ (function space), we now optimize over $w$ and $\theta$ (parameter space).

Assume generator and discriminator are extremely expressive, the analysis of optimization on parameter space gives the same results.

Results
Results of Case Study

Figure 5: Training process of JS-GAN and RS-GAN for two-cluster data. True data are red, fake data are blue. RS-GAN escapes from mode collapse faster than JS-GAN.

Figure 6: (a) and (b): Evolution of $D$ loss over iterations. RS-GAN is 3-4× faster than JS-GAN. (c) For JS-GAN training in (a), we plot $(Y, D)$ together at iteration 2800. $Y$ are represented in blue points, and they are near $c_1 = 0$. $D$ is near the optimal $D^*(s_{1\alpha})$ since $D(0) \approx 1/3$ and $D(4) \approx 1$. Interestingly, this bad attractor $(Y, D)$ is similar to the one discussed in Fig. 1, so the intuition of “local-min” is verified in (c).

Table 2: Inception score (IS) (higher is better) and Frechet Inception distance (FID) (lower is better) for JS-GAN, WGAN-GP and RS-GAN on CIFAR-10 and STL-10. We also show FID gap between JS-GAN and RS-GAN and show the relative model size of narrow nets vs. regular nets (“regular”: CNN and ResNet of [67]).
Conclusion

- Analyze the landscape of JS-GAN and generalize the results to the standard GANs.
- The results show that the minimization problem has many sub-optimal local minima and each leads to a model collapse.
- Prove minimization problem of the relativistic pairing GANs has no local minima.
- Conduct experiments that support the landscape theories.
