NF 2: Autoregressive Flows
CS 598: Deep Generative and Dynamical Models

Instructor: Arindam Banerjee

October 5, 2021
Variational Inference with Normalizing Flows

- Goal is to optimize the ELBO
  \[ \mathcal{L}(x; \theta, \phi) = \mathbb{E}_{q_\phi(z|x)}[\log p_\theta(x, z) - \log q_\phi(z|x)] \]

- Create flexible \( q(z|x) \) in two steps
  - Inference network to get \( q(z_0|x) \)
    \[ q(z_0|x) \sim \mathcal{N}(z_0|\mu(x), \sigma^2(x)) \]
  - Normalizing flow to get \( z_t = f_t(z_{t-1}; x)) \), \( t = 1, \ldots, T \)
    \[ \log q(z_T|x) = \log q(z_0|x) - \sum_{t=1}^{T} \log \det \left| \frac{dz_t}{dz_{t-1}} \right| \]
Linear Vector Autoregressive (VAR) Models

- Classical order $k$ linear VAR model

$$y_t = A_1 y_{t-1} + A_2 y_{t-2} + \cdots + A_k y_{t-k} + c + e_t$$

- $y_t, c, e_t \in \mathbb{R}^d$
- $A_t \in \mathbb{R}^{d \times d}$

- The error terms $e_t$ are unbiased and uncorrelated
  - Unbiased: $\mathbb{E}[e_t] = 0$
  - Covariance structure: $\mathbb{E}[e_t e^T_t] = \Sigma$
  - Uncorrelated: $\mathbb{E}[e_t e^T_{\tau}] = 0$, $\tau < t$

- For Gaussian errors, uncorrelated implies independent
Sample a noise vector $\epsilon \sim \mathcal{N}(0, \mathbb{I})$

Autoregressive model with non-linear mean and variances

\[
y_0 = \mu_0 + \sigma_0 \cdot \epsilon_0
\]
\[
y_i = \mu_i(y_{1:i-1}) + \sigma_i(y_{1:i-1}) \cdot \epsilon_i
\]

$\mu_i, \sigma_i$ can be non-linear (deep) functions

Sampling is sequential, scales with dimensionality

- Not suitable for posterior sampling
- Variational inference needs sampling, not suitable for VI
Inverse Autoregressive Transformations

- Inverse of autoregressive transformation
  \[ \epsilon_i = \frac{y_i - \mu_i(y_{1:i-1})}{\sigma_i(y_{1:i-1})} \]
  - Maps 'signal' \( y_i, y_{1:i-1} \) to 'noise' \( \epsilon_i \)

- Inverse autoregressive transformation as normalizing flows
  - Given \( y \), \( \epsilon \) can be computed directly, non-sequentially
  \[ \epsilon = \frac{y - \mu(y)}{\sigma(y)} \]
  - Has a simple Jacobian determinant
  \[ \log \det \left| \frac{d\epsilon}{dy} \right| = \sum_{i=1}^{D} - \log \sigma_i(y) \]
Inverse Autoregressive Flows (IAF)

- Initial encoder network gives $\mu_0(x), \sigma_0(x)$, extra output $h$
- With $\epsilon \sim \mathcal{N}(0, I)$, initial latent variable
  \[ z_0 = \mu_0 + \sigma_0 \odot \epsilon \]
- Flow consists of a chain of transformations
  \[ z_t = \mu_t + \sigma_t \odot z_{t-1} \]
  - Autoregressive networks $\mu_t(z_{1:t-1}, h)$ and $\sigma_t(z_{1:t-1}, h)$
- Overall model autoregressive w.r.t. $z_{1:t-1}$
  - Jacobians $\frac{d\mu_t}{dz_{t-1}}, \frac{d\sigma_t}{dz_{t-1}}$ are triangular with 0 diagonals
IAF Properties

- Jacobians $\frac{dz_t}{dz_{t-1}}$ is triangular with $\sigma_t$ on diagonals
- Determinant is $\prod_{i=1}^{D} \sigma_{t,i}$
- Final iterate is given by
  \[
  \log q(z_T|x) = - \sum_{i=1}^{D} \left( \frac{1}{2} \epsilon_i^2 + \frac{1}{2} \log 2\pi + \sum_{t=0}^{T} \log \sigma_{t,i} \right)
  \]
- Numerically stable version
  \[
  [m_t, s_t] = \text{ARNN}[t](z_{t-1}, h; \theta)
  \]
  \[
  \sigma_t = \text{sigmoid}(s_t)
  \]
  \[
  z_t = \sigma_t \odot z_{t-1} + (1 - \sigma_t) \odot m_t
  \]
- Reverse the ordering of variables after each step
Figure 2: Like other normalizing flows, drawing samples from an approximate posterior with Inverse Autoregressive Flow (IAF) consists of an initial sample $z$ drawn from a simple distribution, such as a Gaussian with diagonal covariance, followed by a chain of nonlinear invertible transformations of $z$, each with a simple Jacobian determinants.
**Algorithm 1**: Pseudo-code of an approximate posterior with Inverse Autoregressive Flow (IAF)

**Data:**
- \( x \): a datapoint, and optionally other conditioning information
- \( \theta \): neural network parameters
- \( \text{EncoderNN}(x; \theta) \): encoder neural network, with additional output \( h \)
- \( \text{AutoregressiveNN}[^*](z; h; \theta) \): autoregressive neural networks, with additional input \( h \)
- \( \text{sum}(\cdot) \): sum over vector elements
- \( \text{sigmoid}(\cdot) \): element-wise sigmoid function

**Result:**
- \( z \): a random sample from \( q(z|x) \), the approximate posterior distribution
- \( l \): the scalar value of \( \log q(z|x) \), evaluated at sample \( 'z' \)

\[
\begin{align*}
[\mu, \sigma, h] &\leftarrow \text{EncoderNN}(x; \theta) \\
\epsilon &\sim \mathcal{N}(0, I) \\
z &\leftarrow \sigma \circ \epsilon + \mu \\
l &\leftarrow -\text{sum}(\log \sigma + \frac{1}{2} \epsilon^2 + \frac{1}{2} \log(2\pi)) \\
\text{for } t &\leftarrow 1 \text{ to } T \text{ do} \\
\quad [m, s] &\leftarrow \text{AutoregressiveNN}[t](z; h; \theta) \\
\quad \sigma &\leftarrow \text{sigmoid}(s) \\
\quad z &\leftarrow \sigma \circ z + (1 - \sigma) \circ m \\
\quad l &\leftarrow l - \text{sum}(\log \sigma) \\
\text{end}
\end{align*}
\]
Figure 3: Overview of our ResNet VAE with bidirectional inference. The posterior of each layer is parameterized by its own IAF.
Table 1: Generative modeling results on the dynamically sampled binarized MNIST version used in previous publications (Burda et al., 2015). Shown are averages; the number between brackets are standard deviations across 5 optimization runs. The right column shows an importance sampled estimate of the marginal likelihood for each model with 128 samples. Best previous results are reproduced in the first segment: [1]: (Salimans et al., 2014) [2]: (Burda et al., 2015) [3]: (Kaae Sønderby et al., 2016) [4]: (Tran et al., 2015)

Two families: AR models and NF models

**Normalizing Flows**
- Sequence of invertible transformations of a base distribution
- “… not well suited for density estimation …”

**Autoregressive density estimation**
- Chain rule $p(x) = \prod_i p(x_i|x_{1:i-1})$
- Sequential and sensitive to variable order
Autoregression as Normalizing Flows

- **Autoregression with Gaussians**
  \[ p(x_i|x_{1:i-1}) = \mathcal{N}(x_i|\mu_i, (\exp \alpha_i)^2) \], \( \mu_i = f_{\mu_i}(x_{1:i-1}), \alpha_i = f_{\alpha_i}(x_{1:i-1}) \)

- **Generating samples using** \( u_i \sim \mathcal{N}(0, 1) \)
  \[ x_i = u_i \exp \alpha_i + \mu_i, \quad \mu_i = f_{\mu_i}(x_{1:i-1}), \alpha_i = f_{\alpha_i}(x_{1:i-1}) \]

- **With** \( x = f(u), u \sim \mathcal{N}(0, I) \), consider \( f^{-1} \)
  - **Given** \( x \), \( u = f^{-1}(x) \) is easy to compute
    \[ u_i = (x_i - \mu_i) \exp(-\alpha_i), \quad \mu_i = f_{\mu_i}(x_{1:i-1}), \alpha_i = f_{\alpha_i}(x_{1:i-1}) \]
  - **Jacobian of** \( f^{-1} \) is triangular by design with diagonal \( \exp(-\alpha_i) \)
    \[ \left| \det \frac{\partial f^{-1}}{\partial x} \right| = \exp \left( - \sum_{i} \alpha_i \right), \quad \alpha_i = f_{\alpha_i}(x_{1:i-1}) \]
Masked Autoregressive Flows (MAF)

- Use autoregressive model as a flow
- Assess generative model by checking if $u = f^{-1}(x)$ is Gaussian
  $$u_i = (x_i - \mu_i) \exp(-\alpha_i), \quad \mu_i = f_{\mu_i}(x_{1:i-1}), \alpha_i = f_{\alpha_i}(x_{1:i-1})$$
- Stack a set of AR models $M_1, \ldots, M_k$
- Implement $\{f_{\mu_i}, f_{\alpha_i}\}$ with masking, avoid sequential computation
  - Use MADE, autoregressive property implemented by masking
- MAF is stacked MADE, each layer is a MADE
Figure 1: (a) The density to be learnt, defined as $p(x_1, x_2) = \mathcal{N}(x_2 | 0, 4)\mathcal{N}(x_1 | \frac{1}{4}x_2^2, 1)$. (b) The density learnt by a MADE with order $(x_1, x_2)$ and Gaussian conditionals. Scatter plot shows the train data transformed into random numbers $u$; the non-Gaussian distribution indicates that the model is a poor fit. (c) Learnt density and transformed train data of a 5 layer MAF with the same order $(x_1, x_2)$. 
Both use flows based autoregression

IAF generates \((\mu_i, \alpha_i)\) from past random numbers

\[ x_i = u_i \exp \alpha_i + \mu_i, \quad \mu_i = f_{\mu_i}(u_{1:i-1}), \quad \alpha_i = f_{\alpha_i}(u_{1:i-1}) \]

- Generate samples and compute their likelihood in one pass
- Likelihood of new \(x\): sequentially generate \(u\), needs \(D\) passes

MAF generates \((\mu_i, \alpha_i)\) from past data variables

\[ x_i = u_i \exp \alpha_i + \mu_i, \quad \mu_i = f_{\mu_i}(x_{1:i-1}), \quad \alpha_i = f_{\alpha_i}(x_{1:i-1}) \]

- Likelihood of any \(x\) in one pass
- Sampling \(x\) is sequential, needs \(D\) passes
MAF and Real NVP

- Real NVP uses coupling layers
  \[ x_{1:d} = u_{1:d} \]
  \[ x_{d+1:D} = u_{d+1:D} \odot \exp \alpha + \mu, \quad \mu = f_{\mu}(u_{1:d}), \alpha = f_{\alpha}(u_{1:d}) \]

- Stack coupling layers by permuting variables
- Special case \( \alpha = 0 \) corresponds to NICE (NF1, first paper)

- Special cases of MAF (and IAF), which have fine-grained control
  \[ x_i = u_i \exp \alpha_i + \mu_i, \quad \mu_i = f_{\mu_i}(x_{1:i-1}), \alpha_i = f_{\alpha_i}(x_{1:i-1}) \]

- Generating samples, i.e., draw \( x \sim p(x) \)
  - One pass for Real NVP and IAF, \( D \) passes for MAF

- Likelihood computation, i.e., given \( x \), compute \( p(x) \)
  - One pass for Real NVP and MAF, \( D \) passes for IAF
Table 1: Average test log likelihood (in nats) for unconditional density estimation. The best performing model for each dataset is shown in bold (multiple models are highlighted if the difference is not statistically significant according to a paired t-test). Error bars correspond to 2 standard deviations.
